

Q. 1) Define a structure in C & C++?

This structure should hold the variables for student type. compute the size of struct manually

a. use size of function to display the size

crosscheck if both are same (or) not
Justify the answer.

A structure (defined using the struct keyword) is a user defined data type in C and C++ that groups logically related variables of different data type

Types under a single name.

In C

Ex: #include <stdio.h>

struct student {

char name[20];

int rollno;

};

int main() {

struct student s1;

s1.name = "Arshina";

s1.roll = 29;

printf("Student name: %s\n", s1.name);

printf("Rollno: %d\n", s1.roll);

```
Ex:- #include <iostream>
using namespace std;
struct student {
    string name;
    int roll no;
    void display() {
        cout << "Name: " << name << endl;
        cout << "Roll No: " << roll << endl;
    }
};
```

```
void  
int main() {
```

```
    Student S1;
```

```
    S1.name = "Fortnum";
```

```
    S2.roll = 29;
```

```
    S1.display;
```

```
}
```
